Effect of Tinidazole on Norfloxacin Disposition

Mona El Assal ,Mona Ibrahim Abdel tawab ElAssal and sally Ali Helmy

Abstract

Co-administration of norfloxacin (NFX) and tinidazole (TNZ) has been used for the treatment of gastrointestinal and urinary tract infections. Concomitant oral administration

of NFX with TNZ may affect NFX absorption and consequently its blood concentration and

pharmacological effect. The present study was undertaken to investigate the effect of TNZ at

the usual clinical dosage on the pharmacokinetics of NFX in healthy volunteers. This study

was conducted as an open-label, randomized, two-way crossover experimental design. After

an overnight fast, subjects were randomized to receive a single oral dose of NFX 400 mg

alone and the fixed-dose combination (FDC) of NFX /TNZ 400 mg/600mg on two different $\,$

occasions separated by 1 week washout period between treatments. Blood samples were

collected up to 24 h postdose, and plasma was analyzed for NFX concentrations by using

HPLC. The pharmacokinetic properties of NFX after FDC administration were compared with

NFX administered alone. Twelve healthy subjects were enrolled (6 in each part), and all subjects

completed the study. None of the participants showed any sign of adverse drug reactions during

or after the completion of the study. The 90% confidence interval (CI) between NFX alone and

when co-administered with TNZ indicated the presence of an interaction between NFX and

TNZ, which would significantly increase the systemic rate and exposure of NFX absorption.

The co-administration of TNZ with NFX increased the AUC and Cmax of NFX significantly

compared with administration of NFX alone. The AUC and Cmax of NFX alone were 6.0° g.hr/

mL (2.3-9.8) and 0.87" g/mL (0.4-1.6), respectively whereas the corresponding AUC and Cmax

values after administration of FDC were 7.1" g.hr/mL (4.0-10.6) and 0.97" g/mL (0.4-1.7),

respectively. The respective geometric mean ratios of NFX for AUC and Cmax with TNZ were

1.197 [90% CI, 0.941-1.522] and 1.087 (90% CI, 0.807 -1.463) compared with NFX alone.

Both Tmax and Ka of NFX showed a significant decrease after administration of the combination

compared to administration of NFX alone. The peak plasma concentration reached

at 1.3 h

(0.6-2.4) and 1.9 h (0.4-4.4) after oral administration of FDC and NFX alone, respectively.

Both NFX and TNZ were well tolerated. The interaction of TNZ with fluroquinolones

should be investigated to determine whether this interaction is limited to NFX or if other

fluroquinolones have the same pharmacokinetic interactions. Further studies are necessary to

determine the role of P-gp and other transporters on NFX disposition and pharmacokinetics.

Additionally, the influence of TNZ on the physiological activity of GIT should be investigated.
