Abstract

Background: Several studies have hypothesized that oral infection may increase the risk of preeclampsia. Therefore, our study explores the relationship between chronic oral infection and the risk of development of preeclampsia in Egyptian women. Subjects and methods: Forty preeclamptic women with periodontitis and/or pericoronitis (group I) and 40 control subjects having periodontitis and/or pericoronitis (group II) were subjected to microbiological assessment of samples on different culture media and multiplex PCR. TNF-α was determined in gingival crevicular fluid (GCF), saliva and serum by ELISA and real-time PCR. Results: There was no statistically significant difference between the two groups as regards to subgingival plaque and pericoronal pseudo-pocket organisms revealed by culture and PCR, and as regards to blood sample organisms revealed by culture. The total number of anaerobes was higher in preeclamptic group than controls it was (97 vs. 70) in blood samples and (82 vs. 28) in placental samples respectively. While PCR results of placental sample of the preeclampsia group showed statistically significantly higher prevalence of Aggregatibacter actinomycetemcomitans, Eikenella corroden and Prevotella intermedia than that of the control. There was a statistically significant difference between the two groups as the level of TNF-α by ELISA in GCF (P-value = 0.021), in saliva (P-value = 0.043) and in serum (P-value = 0.021). Conclusion: There was a relationship between chronic oral infection and preeclampsia, so treatment of oral infection during pregnancy may represent a novel approach and preventive strategy that reduce oral bacterial load which would decrease the incidence of preeclampsia. Keywords: Periodontitis-pericoronitis-preeclampsia-risk factor.
